A sump pump that is powered by electricity or water pressure. During storms when electrical power is lost the pump can operate on water pressure until electrical power is restored. The sump pump is comprised of a venturi **101**, electric pump **102**, float operated valve **104**, and level switch **105**, **205**, or level controller/sensor **305/314** depending on the type of level sensing used.

ELECTRIC OR WATER POWERED SUMP PUMP**FIELD OF INVENTION**

The present invention relates to the problem of maintaining the operation of a sump pump during a power outage.

BACKGROUND

Home owner losses from flooded dwellings can be hundreds to thousands of dollars. Many homes are protected by two sump pumps, supplied by different companies, in an attempt to maintain sump pump operation during a power outage.

Typically, a sump pump powered from the grid is backed up by a battery or a water powered sump pump. The battery backup pump will run during a power outage until the batteries are exhausted (several days or more). A water powered pump will operate indefinitely as long as a source of pressurized water is available, such as city water. As city water is a reliable source of pressurized water, water powered sump pumps are becoming very popular as a reliable backup sump pump to an electrically powered sump pump.

The water powered sump pump (venturi pump) has no moving parts and can run for years without maintenance. By using a venturi pump as the primary sump pump, but powered by electricity, the same venturi pump can switch to a source of pressurized water to continue operation when power fails, and then, switch back to electricity when power is restored.

Operating such a sump pump continuously on city water would be expensive and wasteful. By producing a local source of pressurized water with an electrically powered pump, the venturi sump pump can continuously operate through power outages. Further, this sump pump will have no moving wearing parts in the sump making maintenance easier. All the equipment is wall mounted above the sump, safe and dry. A dual power sump pump that is more reliable and easier to maintain is desirable.

SUMMARY OF INVENTION

The object of this invention is to improve reliability and ease of maintenance for a sump pump that acts as its own backup.

Hence, a venturi powered by pressurized water is employed to create a vacuum sufficient to draw sump water up into the venturi and discharge the sump water with the spent pressurized water.

By adding a local source of pressurized water created by an internal electrically powered pump, the venturi can act as its own backup, using locally produced pressurized water from an internal electrically powered pump when available, and automatically switching to city water when grid power is lost.

The internal electrically powered pump is operated by a level switch that decides when the water level in the sump requires the sump to operate. On power failure, the sump water level will then trigger a solenoid valve to supply pressurized city water to the venturi to maintain sump pump operation. When power is restored, pump will automatically switch back to operation with electrical power.

The invention provides a dual power sump pump that will act as its' own backup pump that improves reliability, and ease of maintenance in a single pump package.

BRIEF DESCRIPTION OF THE DRAWINGS

Having described the invention in general terms, reference will now be made to the accompanying drawings, which are not necessarily drawn to scale, and where in:

2

FIG. 1 shows a block diagram of a dual powered sump pump using a mechanical level sensor to operate the electrically powered pump and a float valve to send city water to the venturi.

FIG. 2 shows a block diagram of a dual powered sump pump using a mechanical level sensor to operate the electrically powered pump and a control valve to send city water to the venturi.

FIG. 3 shows a block diagram of a dual powered sump pump using an electronic level sensor to operate the electrically powered pump and a control valve to send city water to the venturi.

DETAILED DESCRIPTION OF THE INVENTION

The present invention will now be described more fully hereinafter with reference to the accompanying drawings, in which some embodiments of the invention are shown. Indeed, this invention may be embodied in many different forms and should not be construed as limited to the embodiments set forth herein; rather these embodiments are provided by way of example so this disclosure will satisfy applicable legal requirements. Like numbers refer to like elements throughout.

FIG. 1 illustrates a dual powered sump pump using separate level sensors. The venturi **101** requires a source of pressurized water to operate. The primary source of pressurized water is an internal electrical pump **102** installed in loop **103**. Pump **102** is controlled by level switch **105**. The venturi pump **101** also has a secondary source of pressurized water, typically from a city water supply. City water flow to the venturi pump is regulated by the float valve **104**. The level switch **105** operates at sump water level **110** which are below the operating water level **111** for the float valve **104**.

When operating on electrical power the pump **102** takes a small amount of water from discharge **106** and pressurizes and feeds this water through the check valve **107** to the venturi **101**. With float valve **104** normally closed, all the pressurized water from pump **102** passes through the venturi pump **101**. This small pressurized flow creates a vacuum that will draw sump water up through the sump suction line **109** and into venturi **101**. The combined water flows are sent to the discharge **106**.

When power fails, the sump **100** water level will rise above water level **110** to water level **111** and open float valve **104**. City water under pressure will be directed to the venturi pump **101** to maintain operation. Check valve **107** blocks city water from passing bypassing through the electrical pump **101**, and thereby avoiding the venturi **101**.

Check valve **108** in the sump suction line **109** maintains a prime in the venturi **101** and loop **103**.

FIG. 2 illustrated a dual powered sump pump identical to the sump pump in FIG. 1, but using a single mechanical level switch **205** to control the operation of the pump **202** and a solenoid valve **204**. The level switch **205** has upper and lower switch points. The lower switch point operates pump **202**, while the upper switch point operates the solenoid valve **204**. A battery **213** powers the level switch **205** and the solenoid valve **204**. Battery **213** is charged from the grid.

FIG. 3 illustrated a dual powered sump pump identical to the sump pump in FIG. 1, but using a single electronic level sensor/controller **305** to control the operation of the pump **302** and a solenoid valve **304**. The level sensor **305** has upper and lower set points. The lower set point operates pump **302**, while the upper set point operates the solenoid valve **304**. Level sensor **305** can also monitor and log sump water flow-rates and send system information or operational problems to

the home owner by wireless or wireless/internet links. For instance, the home owner can be notified by a text message if the power is out and the sump pump is running on water power.

The invention claimed is:

5

1. A dual powered sump pump comprising:
an internal electric pump;
a venturi; and
an actuator,

wherein the actuator triggers the internal electric pump to 10
pressurize and feed water which has accumulated in a
sump to the venturi, thereby creating a vacuum to pump
accumulated water from the sump, and in the absence of
electricity, the actuator triggers the flow of water from an
external city supplied water source to the venturi, 15
thereby creating a vacuum to pump accumulated water
from the sump during a power outage.

2. The dual powered sump pump of claim 1 wherein the
actuator is a float switch which triggers the internal electric
pump and alternatively triggers a solenoid valve which con- 20
trols the flow of the external city supplied water during the
power outage.

3. The dual powered sump pump of claim 1 wherein the
actuator is a single electronic level sensor which triggers the
internal electric pump and alternatively triggers a solenoid 25
valve which controls the flow of the external city supplied
water during the power outage.
